Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

## Description

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

[0001] The present invention relates to a fabric arrangement and method for controlling fluid flow and, more particularly, to a fabric arrangement and method for controlling fluid flow which may be utilized with friction elements.

#### 2. Description of Related Art

[0002] In clutches, brakes, automatic transmissions, limited slip differentials, hoists and similar friction power transmission and energy absorption devices, there is generally provided one or more sets of cooperating members, in which one of the cooperating members drives the other. It is not uncommon for these cooperating members to move in a cooling medium or liquid, which is generally some type of lubricating oil, and frequently the oil is force circulated about and between the engaging surfaces of the cooperating members so as to continuously lubricate and cool them. In order to accomplish circulation of the cooling medium within blocker rings, clutch plates, transmission bands and the like, the prior art has provided grooves or slots directly in the engaging surfaces of one or both of the cooperating members or in friction material affixed thereto. For example, such a friction material may be a brass coating or a paper liner as seen in U.S. Patent 4,267,912 to Bauer et al., U.S. Patent 4,878,282 to Bauer, and U.S. Patent 4,260,047 to Nels.

[0003] Forming grooves within the friction material of cooperating members not only adds complexity to the manufacture of such friction material and the power transmission-absorption device, but also is limited in its ability to circulate cooling medium therethrough. In order to reduce or eliminate the hydrodynamic friction stemming from oil or cooling medium lying on the surface of the friction material engaging the driving member, an improved friction material for circulating the cooling medium is required, especially one which may be varied according to desired parameters.

[0004] Prior art friction materials also include certain pyrolytic carbon friction materials as seen in U.S. Patent 4,700,823 to Winckler and U.S. Patent 4,291,794 to Bauer. In such friction material, a meshed cloth substrate formed of carbon fibers is provided with a coating of carbon or other material being deposited on the fibers by chemical vapor deposition. This type of friction material has the characteristic of a relatively open mesh which allows ready penetration by an adhesive for improved bonding, as well as a certain degree of porosity therethrough. However, as pointed out in the '794 patent, grooving of such material is still provided in order to permit the flow of the cooling fluid between the friction

faces of the cooperating members of the power transmission or energy absorption assembly. This type of friction material also does not easily provide highly bonded fibers at a friction surface of the material nor does it achieve a highly controlled texture as needed. Moreover, it has been found that such friction material is difficult to compress to a desired thickness, such as during the process of bonding it to a member.

[0005] It is also seen that such pyrolytic friction material utilizes as its substrate a plain weave of the type illustrated in Fig. 6, where both the fill and warp yarns of the material contact the cooperating element. Such an arrangement leads to increased wear of the friction material due to the effect on the yarns oriented perpendicularly to the direction of motion for the cooperating element. Therefore, an additional desired feature not found in prior art devices is a friction surface texture which reduces wear on the friction material.

[0006] It is the object of the invention to provide a friction facing material as disclosed for example in US-A-4 291 794 and a method for making a friction member using such friction facing material, wherein the friction facing material can easily be brought into the shape of the friction member.

[0007] This object is achieved by a friction facing material having the features defined in claim 1 and a method for making a friction member comprising the features as defined in claim 8. Preferred embodiments are defined in the dependent subclaims.

[0008] In accordance with a preferred embodiment of the present invention, a material is disclosed having a plurality of first yarns and a plurality of second yarns woven with the plurality of first yarns to form a predetermined arrangement in order to control fluid flow.

[0009] A further preferred embodiment comprises a friction power absorption or power transmission assembly of the type having means for changing the relative position between a friction material and an opposing surface material from a position of complete engagement to a position of complete disengagement, the assembly including a first member, a second opposing member, a friction facing material affixed to one of the first and second members, the friction facing material being a woven fabric having a plurality of first yarns positioned in substantially parallel relationship to each other and a plurality of second yarns woven in serpentine fashion over and under the first yarns to form a texture having a plurality of plateaus and valleys, wherein only the plateaus of the woven fabric engage the other of the members, and means for introducing a liquid cooling medium between the first and second members.

[0010] Further, a method of making a friction facing material for use in a power absorption-transmission assembly is disclosed involving the steps of weaving a plurality of yarns in a predetermined pattern so as to form a woven fabric having a texture with a plurality of plateaus and valleys therein, fixing the woven fabric yarns in position, and providing an adhesive to the woven fab-

ric.

**[0011]** Accordingly, there is provided a friction facing material for use with cooperating members of a power transmission-absorption device which is able to circulate cooling medium therethrough without the need for machining additional grooves or slots.

**[0012]** Further, a friction facing material is provided for use with cooperating members of a power transmission-absorption device which can be oriented with respect to the direction of movement between the cooperating members so as to reduce wear and spin loss thereof.

**[0013]** Preferably, a friction facing material is provided for use with cooperating members of a power transmission-absorption device which can be woven so as to include flow channels of desired size and orientation.

#### BRIEF DESCRIPTION OF THE DRAWING

**[0014]** While the specification concludes with claims particularly pointing out and distinctly claiming the present invention, it is believed that the same will be better understood from the following description taken in conjunction with the accompanying drawing in which:

Fig. 1 is a front view of a blocker ring having a friction facing material bonded thereon in accordance with the present invention;

Fig. 2 is an enlarged, partial cross-sectional view of the blocker ring in Fig. 1;

Fig. 3 is an exploded perspective view of the blocker ring depicted in Figs. 1 and 2 with its cooperating elements in a typical power transmission-absorption assembly;

Fig. 4A, which is shown on the same sheet as Fig. 2, is an enlarged, diagrammatic side view of the friction facing material of Figs. 1-3 prior to bonding;

Fig. 4B, which is shown on the same sheet as Fig. 2, is a partial, magnified view of a single yarn in the friction facing material of Fig. 4A;

Fig. 4C, which is shown on the same sheet as Fig. 2, is a partial, diagrammatic side view of the channels defined in the friction facing material of Fig. 4A, where the plateaus and low points are depicted in their state after bonding;

Fig. 5 is a photograph of the friction facing material depicted in Fig. 4A;

Fig. 6 is a photograph of a prior art friction facing material having a plain weave;

Fig. 7 is a diagrammatic depiction of several exemplary weave styles which may be employed in the friction facing material of the present invention;

Fig. 8 is a diagrammatic depiction of a friction facing material according to the prior art being circumferentially arranged as non-interlocking arcuate segments on a clutch plate;

Fig. 9 is a diagrammatic depiction of a friction facing material according to the prior art being circumferentially arranged as interlocking arcuate segments

on a clutch plate;

Fig. 10 is a diagrammatic depiction of a friction facing material according to the prior art being arranged as a plain cut full ring on a clutch plate;

Fig. 11 is a diagrammatic depiction of a friction facing material according to the prior art being arranged as an edge wound full ring on a clutch plate; Fig. 12A is a diagrammatic depiction of a strip of the friction facing material of the present invention, where a plurality of notches have been formed therein;

Fig. 12B is a diagrammatic depiction of the strip of friction facing material shown in Fig. 12A arranged on a clutch plate;

Fig. 13A is a diagrammatic depiction of a strip of friction facing material of the present invention, where a plurality of lances have been formed therein;

Fig. 13B is a diagrammatic depiction of the strip of friction facing material shown in Fig. 13A arranged on a clutch plate;

Fig. 14 is a diagrammatic depiction of friction facing materials having different weave patterns, including some with several layers of different weave patterns, being circumferentially arranged as non-interlocking arcuate segments on a clutch plate;

Fig. 15 depicts an enlarged, diagrammatic side view of an alternate embodiment for the friction facing material of the present invention;

Fig. 16 is an enlarged diagrammatic side view of a third embodiment of the friction facing material of the present invention; and

Fig. 17 is an enlarged diagrammatic side view of a fourth embodiment of the friction facing material of the present invention.

#### DETAILED DESCRIPTION OF THE INVENTION

**[0015]** Referring now to the drawing in detail, wherein identical numerals indicate the same elements throughout the figures, Fig. 1 depicts a blocker ring 10 including a friction facing material 15 affixed to an inner annular wall 12 thereof in conjunction with the present invention. It will be understood that blocker ring 10 is one element of a power transmission or absorption assembly such as that utilized in clutches, brakes, automatic transmissions, limited slip differentials, hoists and other similar friction power transmission and energy absorption devices. One example of the environment in which blocker ring 10 may be utilized is disclosed in U.S. Patent 4,732,247 to Frost. While blocker ring 10 and friction facing material 15 discussed herein may be utilized with such friction power transmission and energy absorption devices, it will be understood that friction facing material 15 of the present invention is not limited to such specific devices. For example, friction facing material 15 may be utilized in other friction devices such as clutch plates, torque converter clutches, and transmission bands.

Moreover, it is contemplated that the material of the present invention could be utilized in other devices where the control of fluid flow is required, such as gas-kets, filters, nozzles, and the like.

**[0016]** As seen in Fig. 1, blocker ring 10 includes three raised lugs 14 equally spaced at 120° intervals around blocker ring 10. Lugs 14 may be nested within associated hub notches of another member 17 of the assembly (not shown). As best seen in Fig. 3, blocker ring 10 also has a toothed or splined surface 16 formed on the outer circumference thereof which is engagable with member 17 of the power transmission-absorption assembly and thereby able to clock or rotate member 17 in accordance with a cooperating friction element 18 causing movement along inner annular wall 12. As best seen in Figs. 1 and 2, friction facing material 15 of the present invention is affixed to inner annular wall 12 of blocker ring 10 by means of a layer of adhesive 20, such as nitrile phenolic adhesive. It will be understood that cooperating friction element 18 (see Fig. 3) is movable along a longitudinal axis 19 in order to engage and disengage blocker ring 10.

**[0017]** Fig. 4A depicts a diagrammatic side view of friction facing material 15 in its initial state, which includes a plurality of substantially linear fill yarns 25 arranged substantially parallel to each other. A plurality of substantially parallel warp yarns 30 shown in a sinusoidal side view in Fig. 4A are woven with fill yarns 25 in a serpentine fashion (i.e., over and under adjacent fill yarns 25) to form a series of high points 32 (known as "plateaus") and a series of low points 34 (known as "adhesion points"). Positioned between each warp yarn 30 is a second set of warp yarns 31, which also are woven in serpentine fashion with fill yarns 25 to form a series of plateaus 33 and a series of adhesion points 35. However, in order to maintain the construction of friction facing material 15, warp yarns 31 are out of phase with warp yarns 30 so that plateaus 32 of warp yarns 30 are opposite adhesion points 35 of warp yarns 31 and adhesion points 34 of warp yarns 30 are opposite plateaus 33 of warp yarns 31. By weaving warp yarns 30 and 31 with fill yarns 25 in this way, a plurality of upper channels 36 and 37 (known as "valleys") are formed between adjacent plateaus 32 and adjacent plateaus 33, respectively. Likewise, a plurality of lower channels 38 and 39 may be formed between adjacent adhesion points 34 and adhesion points 35.

**[0018]** Further, as best seen in Fig. 5, fill yarns 25 may be tensioned by a greater amount than warp yarns 30 and 31, which also facilitates defining the formation of upper channels 36 and 37 in a predetermined or desired weave pattern. Because plateaus 32 and 33 of warp yarns 30 and 31 extend above fill yarns 25, it will be understood that only warp yarn surfaces 30a at plateaus 32 and warp yarn surfaces 31a at plateaus 33 (see Fig. 4A) of friction facing material 15 will engage cooperating friction member 18. In order to reduce wear of friction facing material 15, it is preferred that warp yarns 30 and

31 be positioned so that they are aligned substantially parallel to longitudinal axis 19 (see Figs. 3 and 4A) which is also the direction of relative motion between blocker ring 10 and cooperating friction element 18 to reduce wear on friction facing material 15. It is to be noted that some prior art materials provide warp yarns and fill yarns having engaging surfaces at the same level (see Fig. 6). Consequently, at least some of the yarns are oriented substantially perpendicular to the direction of movement between the cooperating friction members. This, in turn, causes increased wear of the material and/or the cooperating friction member. It should also be noted that while warp yarns 30 and 31 are shown as being woven with substantially linear fill yarns 25, the warp yarns may be substantially linear and two sets of fill yarns may be woven therewith.

**[0019]** It will also be noted that a layer of adhesive 20 is preferably provided so that it engages only adhesive points 34 and 35 of warp yarns 30 and 31, respectively. In this way, both upper channels 36 and 37 and lower channels 38 and 39 (see Fig. 4A) are able to provide flow paths for cooling medium, such as oil, in the power transmission-absorption assembly.

**[0020]** As depicted by the side view representation in Fig. 4C, it will be understood that upper channels 36 and 37, as well as lower channels 38 and 39, preferably have tapered sides 41 and 42. An angle  $\phi$  exists between side walls 41 and 42 and the respective plateaus and adhesion points of warp yarns 30 and 31, with angle  $\phi$  having an angle in the range of 20°-70°, and preferably approximately 45°. By having channels 36-39 formed in this way, exiting of cooling medium therethrough is facilitated due to the Bernoulli theorem.

**[0021]** Further, it will be seen from Fig. 4C that bonding of friction facing material 15 onto a friction element will have a flattening effect on plateaus 32 and 33 of warp yarns 30 and 31, as well as on low points 34 and 35 thereof.

**[0022]** Fill yarns 25 and warp yarns 30 and 31 preferably are carbonized both before and after weaving, with friction facing material 15 preferably being saturated with resin and cured to further fix fill yarns 25 and warp yarns 30 and 31 in the predetermined or desired weave pattern. Even so, friction facing material 15 will generally retain interconnection between upper channels 36 and upper channels 37, while maintaining desired strength characteristics, provided the resin applied thereto is maintained within a range of about 35-50% of friction facing material 15.

**[0023]** With regard to the construction of fill yarns 25 and warp yarns 30 and 31, it has been found that at least nine (9) twists per inch provide suitable definition of the texture for friction facing material 15. In this way, upper channels 36 and 37 and lower channels 38 and 39 thereof become more distinct, thereby increasing the ability of cooling medium to flow therethrough. It will be understood that in order for fill yarns 25 and warp yarns 30 and 31 to have nine twists per inch, an angle  $\theta$  existing

between each fibril 26 and a longitudinal axis 28 (see Fig. 4B), is approximately  $27^\circ$  for a yarn having a diameter of .018 inches. Because there is a direct relationship between angle  $\theta$  and the twists per inch of the yarn, it will be understood that angle  $\theta$  increases as the twists per inch of the yarn increases. Thus, an angle  $\theta$  of  $27^\circ$  or greater for fibrils 26 of each yarn will consequently provide the desired definition of the texture for friction facing material 15, as well as a column strength that will desirably protect against compressive loads.

[0024] It will also be understood that during the yarn manufacturing, the fibrils 26 of warp yarns 30 and 31 will fracture at various points due to the stretching thereof while in a carbonized state. Accordingly, such fibrils 26 may have a length of approximately  $1/4$  to  $1\ 1/2$  inch between fracture points 27 (see Fig. 4C). This construction permits heat to be conducted through the length of a yarn by means of fibrils 26 to fracture points 27, whereupon the heat can then be transmitted to the cooling medium contained within lower channels 38 and 39.

[0025] Another preference of the embodiment herein described is to weave warp yarns 30 and 31 with fill yarns 25 so that plateaus 32 and 33 of warp yarns 30 and 31 have a maximum surface area across friction facing material 15. One manner of increasing such surface area is to weave warp yarns 30 and 31 over more adjacent fill yarns 25 than the number of adjacent fill yarns 25 they are woven under. For example, warp yarns 30 and 31 may be woven over at least two adjacent fill yarns 25 and under at least one fewer adjacent fill yarns 25 alternatively to create a satin weave fabric (see, e.g., the crowfoot satin weave of Fig. 7, where the dark portions represent plateaus 32 and the white portions represent valleys 36 and 37 therebetween). This type of weave creates rectangular plateaus of increased surface area for contacting a cooperating friction element, which is particularly useful in a dry friction element such as brake and clutch facings, whereby improvement in both wear resistance and thermal conductivity is achieved.

[0026] It will be understood, however, that any number of weaves may be utilized or provided with friction facing material 15, including the exemplary weaves shown in Fig. 7 (e.g., plain, crowfoot satin,  $2 \times 2$  basket, 5 HS, 8 HS, Leno,  $2/2$  twill,  $2/1$  twill, non-crimp,  $\pm 45^\circ$  plain,  $\pm 45^\circ$  8 HS, and  $\pm 45^\circ$  crowfoot satin). In fact, such weaves may be selected, designed or utilized to control the size, number, and orientation of upper channels 36 and 37 and lower channels 38 and 39, and consequently the flow paths across friction facing material 15. Accordingly, the amount and velocity of oil or other cooling medium forced across friction facing material 15 can be controlled.

[0027] While a preferred material for friction facing material 15 is carbon, it will be understood that fiberglass, silicone carbide, copper, ceramic, Kevlar, asbestos, or any other material having the required strength, temperature resistance, friction characteristics, and

processibility for the intended application may be utilized.

[0028] It will also be seen from Figs. 15 and 16 that the friction facing material of the present invention may have several layers of fill and warp yarns. Such a multi-layered arrangement not only improves the durability of friction facing material 15, but may include internal cooling vents which further enhances the flow of cooling oil or air therein. Specifically, as seen in Fig. 15, friction facing material 115 contains fill yarns in a dual layer--single layer--dual layer alternating arrangement. A first set of warp yarns 45 is woven over dual layer fill yarns 47a and 47b and under single layer fill yarns 50 in serpentine fashion so as to form a plurality of high points or plateaus 52 and low points 54. A second set of warp yarns 55, which is positioned between adjacent first warp yarns 45, is woven in serpentine fashion under dual layer fill yarns 47a and 47b and over single layer fill yarns 50 (i.e., substantially  $90^\circ$  out of phase with first warp yarns 45) to form high points or plateaus 56 and low points or adhesion points 58 which are opposite low points 54 and plateaus 52, respectively. A third set of warp yarns 60 is woven between dual layer fill yarns 47a and 47b and alternatively over and under single layer fill yarns 50, and is preferably positioned between each adjacent first and second warp yarn 45 and 55, respectively. Accordingly, a plurality of upper cooling vents 65 and lower cooling vents 70 are formed within friction facing material 115. Thus, not only are upper channels 46 between adjacent plateaus 52 of first warp yarns 45 and lower channels 48 between adjacent adhesion points 58 of second warp yarns 55 present for flow of oil discharge thereacross, but internal cooling vents 65 and 70 may also be utilized for the flow of cooling oil or air.

[0029] Another embodiment of the friction facing material (designated by the number 215) is depicted in Fig. 16, where the multi-layered material thereof may be provided or woven to include internal cooling vents 75 of predetermined size and shape. As seen therein, multiple layers of substantially linear fill yarns 77 are arranged in a substantially parallel configuration. It will be seen that two sets of warp yarns 78 and 80 are provided for each layer of fill yarns 77, where first warp yarns 78 and second warp yarns 80 are woven in serpentine fashion with fill yarns 77 but in juxtaposition with respect to each other so that plateaus 82 and 84 and valleys 86 and 88 thereof are approximately  $90^\circ$  out of phase. In order to form a relatively large internal cooling or fluid flow vent or channel 75, certain specified fill strands (such as 77A and 77B shown in phantom in Fig. 16) are omitted from various locations and layers to facilitate providing the cooling vent or channel 75 having a predetermined configuration. Accordingly, first warp yarns 78A, 78B and second warp yarns 80A, 80B normally woven with such omitted fill yarns 77A and 77B may be woven with fill yarns 77 of a different layer (e.g., top and bottom fill yarn layers  $L_1$  and  $L_4$  as shown in Fig. 16). While warp yarns 78A, 78B, 80A, and 80B are shown

as being woven with top and bottom layers  $L_1$  and  $L_4$  of fill yarns 77, thereby providing the greatest available height dimension  $h$  for internal cooling vent 75, it will be understood that fill yarns 77 for any given layer may be omitted to provide internal cooling vents 75 of greater or lesser height  $h$  so long as at least two layers of fill strands 77 remain for weaving purposes. Further, any number of adjacent fill yarns 77 may be omitted to give internal cooling vent 75 a greater or lesser width. To simplify weaving, it is preferred that internal cooling vents or channels 75 be of the same size and shape and repeat in symmetric fashion; however, internal cooling vents 75 may be dissimilar and asymmetric according to the needs of a specific application.

**[0030]** Yet another alternative embodiment for the friction facing material of the present invention, identified by the numeral 315, is depicted in Fig. 17, where only a plurality of substantially parallel yarns (indicated as fill yarns 25 but also may be warp yarns) is provided in conjunction with a layer of scrim 21 on blocker ring 10. In this arrangement, it is preferred that scrim 21 be saturated with adhesive or resin (although separate adhesive layers 20a and 20b may be utilized), whereby yarns 25 may be attached thereto and scrim 21 may be attached to inner annular wall 12 of blocker ring 10. It will be understood that a plurality of substantially linear channels 23 will be formed between adjacent fill yarns 25, which may be utilized to conduct lubricating/cooling fluid across friction facing material 315. Depending on a given application, it will be understood that channels 23 can be oriented on a friction element so as to be at an angle between  $0^\circ$  and  $90^\circ$  to the sliding surface of the friction element.

**[0031]** While friction facing material 15 has been depicted as being positioned on inner annular wall 12 of blocker ring 10, it could just have easily been positioned upon an outer annular wall 22 of cooperating friction element 18 (see Fig. 3). Moreover, as seen in Figs. 8-11 (prior art), 12B, 13B, and 14, friction facing material 15 may be utilized with other types of friction members such as a clutch plate 90, where it is circumferentially positioned around a front or rear surface 92. In addition to the present invention there are several ways for friction facing material 15 to be positioned on clutch plate surface 92, such as non-interlocking arcuate segments 94 (see Fig. 8 prior art). This arrangement forms channels 95 between each arcuate segment 94 which may permit a greater flow of cooling oil than channels 36 and 37, depending on the width of channels 95. Alternatively, friction facing material 15 may include interlocking arcuate segments 96 to form a complete ring around clutch plate surface 92, as seen in Fig. 9 (prior art) and disclosed in U.S. Patent 4,260,047 to Nels. As seen therein, each interlocking segment 96 includes a male extension 98 at a first end and a female receptacle 99 at a second end which may be mated together. The advantages of utilizing arcuate segments 94 or 96 for a ring-shaped object like clutch plate surface 92 are that it

saves material during the blanking process and allows the yarn cooperating with the mating surface to remain approximately parallel with the direction of engagement and disengagement between the friction elements. Nevertheless, friction facing material 15 may be plain cut (or blanked) as a full ring 100 (see Fig. 10 prior art).

**[0032]** Alternatively, a strip of friction facing material 15 may be formed into a flattened hoop 102 so that it may be edge wound about clutch plate surface 92 as seen in Fig. 11 (prior art). Such a strip of friction facing material 15 preferably includes a single male extension 104 at one end and a single female receptacle 105 at the other end so that each end of hoop 102 may be properly mated.

**[0033]** However, according to the present invention and as seen in Figs. 12A and 13A, strips 106 and 107 of friction facing material 15 have notches 108 or lances 109 formed therein. Then, strips 106 and 107 are positioned on clutch plate surface 92 as seen in Figs. 12B and 13B, whereby notches 108 are brought together or lances 109 are pulled apart. In either case, strips 106 and 107 form a multi-sided shape that is sized to fit on clutch plate surface 92.

**[0034]** As shown in Fig. 14, it will be understood that friction facing material of different weaves may be utilized together. There, friction facing material 110, 111, and 112 of various weaves are attached to surface 92 of clutch plate 90 in the form of non-interlocking arcuate segments. It will be seen that friction facing material 110 has the greatest number of flow paths as defined by upper channels 36 and 37 (indicated by white areas 116), thereby permitting the greatest amount of cooling flow. Friction facing material 111 has some flow paths, but fewer than friction facing material 110. Finally, friction facing material 112 has no leakage paths. Thus, depending on the desired amount of cooling medium flow or leakage for a particular area, the friction facing material can be tailored thereto. This may be taken a step further, wherein friction facing material 110, 111, and 112 of different weaves may be radially aligned in several layers as shown in Fig. 14. In this way, complete control of the flow characteristics for a given application may be controlled solely by the weave and arrangement of the friction facing material.

**[0035]** With respect to the method of making friction facing material 15, it will be understood that fill yarns 25 and warp yarns 30 and 31 preferably are initially carbonized in a high temperature oven. Thereafter, fill yarns 25 and warp yarns 30 and 31 are woven in a designated pattern for the particular application so that channels 36, 37, 38 and 39, and possibly cooling vents 65, 70 or 75, are formed to provide the requisite flow paths. In order to fix or lock the woven pattern of fill yarns 25 and warp yarns 30 and 31, friction facing material 15 is then preferably carbonized again in a high temperature oven. To further enhance the locking process, friction facing material 15 preferably is saturated with a resin, such as a phenolic resin, and cured at an appropriate amount

initially in an oven and subsequently at an appropriate amount during the bonding process described hereinafter.

[0036] Once the above steps have been accomplished, adhesive 20 is then applied to one surface of the saturated fabric, such as by lamination. Friction facing material 15 is then ready for blanking, where strips are cut from the rolls of material. Lastly, friction facing material 15 is bonded to a desired friction element, such as blocker ring 10 or clutch plate 90. It has been found that a punch-die arrangement works well to press friction facing material 15 into place on blocker ring 10. For example, the punch may provide pressure in the range of 50-800 lbs. per square inch for approximately 40-100 seconds. In order to prevent adhesive 20 and phenolic resin from wicking into friction facing material 15 during this process, since adhesive 20 will tend to be attracted to the element having a higher temperature, a temperature differential preferably is established between the punch and the die (e.g., the die preferably having a temperature of approximately 550° F and the punch having an initial temperature of approximately 250° F increasing to approximately 400° F during the bond cycle as heat moves from the die through the ring adhesive layer, and friction facing material into the punch).

[0037] Having shown and described the preferred embodiments of the present invention, wherein an inventive friction facing material, the method of making the friction facing material, and a friction element including the friction facing material thereon have been disclosed, it will be understood that further adaptations thereof may be accomplished by appropriate modifications by one of ordinary skill in the art without departing from the scope of the invention. In particular, while the embodiments of the inventive friction facing material have been described herein as preferably including warp yarns weaving with a plurality of substantially linear fill yarns, the opposite thereof is also contemplated (i.e., where fill yarns may be woven with a plurality of substantially linear warp yarns). Further, the specific weaves and materials disclosed herein are also preferred embodiments, since the yarns may also be braided, but should not be deemed limiting on the intent of the present invention.

[0038] It should also be appreciated that the invention could be applied to a wet or dry environment where the control of fluid flow is required, and the channels defined by the predetermined yarn arrangement may be used to channel heating or cooling fluids, including gases and liquids.

#### Claims

1. A friction facing material for adhering to a friction member (10, 92) having the form of a strip (106, 107) made from a plurality of woven yarns arranged in a predetermined pattern so as to form a material

having a texture with a plurality of plateaus and low points therein, wherein an adhesive is laminated to said material **characterized in that:** the strip comprises a plurality of notches (108) or lances (109) for forming and fitting the strip (106, 107) onto the friction member (10, 92).

2. The friction facing material according to claim 1, wherein the strip is substantially straight.

3. The friction facing material according to claims 1 or 2, wherein said notches (108) are arranged so that they can be brought, together for forming and fitting the strip (106) onto the friction member (10, 92)

4. The friction facing material according to one of the preceding claims, wherein said notches (108) are triangular in shape.

5. The friction facing material according to one of the preceding claims, wherein said plurality of notches (108) defines a generally saw-tooth configuration.

6. The friction facing material according to claim 1 or 2, wherein said lances (109) are arranged so that they can be pulled apart for forming and fitting the strip (107) onto the friction member (10, 92).

7. The friction facing material according to one of the preceding claims, wherein said notches (108) or lances (109) are substantially parallel to one another

8. A method for making a' friction member (10, 92), said method comprising the steps of:

providing a friction member (10, 92),  
making a friction facing material by weaving a plurality of yarns in a predetermined pattern so as to form a material having a texture with a plurality of plateaus and low points therein,  
fixing said woven yarns in position,  
laminating an adhesive to said material, blanking the friction facing material in form of a strip (106, 107) comprising a plurality of notches (108) or lances (109),  
bending the strip (106,107) for fitting the strip (106, 107) of friction facing material onto said friction member (10, 92).

9. The method according to claim 8, wherein the friction facing material is blanked into said strip (106, 107) having the notches (108) or lances (109).

10. The method according to claim 8 or 9, wherein the strip (106) is bent so that a first end of the strip (106) is brought towards a second end of the strip (106).

13

EP 0 783 638 B1

14

11. The method according to one of the claims 8 to 10, wherein said method further comprises the steps of: placing said friction facing material (106, 107) on a die; pressing said friction facing material onto said friction member with a punch. 5
12. The method according to claim 11, wherein said method further 15 comprises the step of causing a temperature difference between said die and said punch. 10
13. The method according to one of the claims 8 to 12, wherein said plurality of notches (108) defines a generally saw-tooth configuration. 15
14. The method according to one of the claims 8 to 13, wherein said plurality of notches (108) each comprise a triangular shape. 20
15. The method according to one of the claims 8 to 14, wherein the notches (108) are brought together when bending the strip (106). 25
16. The method according to one of the claims 8 to 12, wherein the lances (109) are pulled apart when bending the strip (107). 30
17. The method according to one of the claims 8 to 16, wherein the notches (108) or lances (109) are substantially parallel to one another. 35
18. The method according to one of the claims 8 to 17, wherein the friction member comprises a clutch plate (92). 40
19. The method according to one of the claims 8 to 17, wherein the friction member comprises a blocker ring (10). 45
- Patentansprüche**
1. Reibbelag-Material zum Anhaften an ein Reibungsbauteil (10, 92), das die Form eines Streifens (106, 107) aufweist, hergestellt aus einer Vielzahl von verwebten Fäden und angeordnet in einem vorgegebenen Muster, um ein Material auszubilden, welches eine Textur mit einer Vielzahl von Höhen und Tiefpunkten aufweist, wobei das Material mit einem Klebemittel beschichtet bzw. laminiert ist, **dadurch gekennzeichnet, dass** der Streifen eine Vielzahl von Kerben (108) oder Einschnitten (109) aufweist, um den Streifen (106, 107) auf dem Reibungsbauteil (10, 92) anzuformen und anzupassen bzw. zu befestigen. 50
2. Reibbelag-Material nach Anspruch 1, wobei der Streifen im Wesentlichen geradlinig ist. 55
3. Reibbelag-Material nach Anspruch 1 oder 2, wobei die Kerben (108) so angeordnet sind, dass sie zusammengefügt werden können, um den Streifen (106) auf dem Reibungsbauteil (10, 92) anzuformen und anzupassen bzw. zu befestigen.
4. Das Reibbelag-Material nach einem der vorhergehenden Ansprüche, wobei die Kerben (108) eine dreieckige Form aufweisen.
5. Reibbelag-Material nach einem der vorhergehenden Ansprüche, wobei die Vielzahl von Kerben (108) im Allgemeinen eine Sägezahn-Anordnung bildet.
6. Das Reibbelag-Material nach Anspruch 1 oder 2, wobei die Einschnitte (109) so angeordnet sind, dass sie auseinander gezogen werden können, um den Streifen (107) auf dem Reibungsbauteil (10, 92) anzuformen und anzupassen bzw. zu befestigen.
7. Reibbelag-Material nach einem der vorhergehenden Ansprüche, wobei die Kerben (108) oder Einschnitte (109) im Wesentlichen parallel zueinander verlaufen.
8. Verfahren zur Herstellung eines Reibungsbauteils (10, 92), wobei das Verfahren folgende Schritte beinhaltet:
- Bereitstellen eines Reibungsbauteils (10, 92),
  - Herstellen eines Reibbelag-Materials durch Verweben einer Vielzahl von Fäden in einem bestimmten Muster um so ein Material zu formen, das eine Textur mit einer Vielzahl von Höhen und Tiefpunkten aufweist,
  - Befestigen der Fäden in der Position,
  - Beschichten bzw. Laminieren des Materials mit einem Klebemittel, Ausstanzen des Reibbelag-Materials in der Form eines Streifens (106, 107), welcher eine Vielzahl von Kerben (108) oder Einschnitten (109) aufweist,
  - Biegen des Streifens (106, 107), um den Streifen (106, 107) aus Reibbelag-Material auf dem Reibungsbauteil (10, 92) anzupassen bzw. zu befestigen.
9. Verfahren nach Anspruch 8, wobei das Reibbelag-Material in die Streifen (106, 107) gestanzt wird, welcher die Kerben (108) oder die Einschnitte (109) aufweist.
10. Verfahren nach Anspruch 8 oder 9, wobei der Strei-

fen (106) so gebogen wird, dass ein erstes Ende des Streifens (106) zu einem zweiten Ende des Streifens (106) gebracht wird.

lité d'encoches (108) ou d'entailles (109) pour former et adapter la bande (106, 107) sur l'élément de frottement (10, 92).

11. Verfahren nach einem der Ansprüche 8 bis 10, wobei das Verfahren ferner folgende Schritte beinhaltet:

- Anordnen des Reibbelag-Materials (106, 107) auf einem Gesenk;
- Pressen des Reibbelag-Materials auf das Reibungsbauteil mit einem Stempel.

- 5 2. Matériau à surface de frottement selon la revendication 1, dans lequel la bande est sensiblement droite.

- 10 3. Matériau à surface de frottement selon la revendication 1 ou 2, dans lequel lesdites encoches (108) sont agencées de telle sorte qu'elles peuvent être rassemblées pour former et adapter la bande (106) sur l'élément de frottement (10, 92).

12. Verfahren nach Anspruch 11, wobei das Verfahren des Weiteren den Schritt des Erzeugens einer Temperaturdifferenz zwischen dem Gesenk und dem Stempel beinhaltet.

- 15 4. Matériau à surface de frottement selon l'une des revendications précédentes, dans lequel lesdites encoches (108) ont une forme triangulaire.

13. Verfahren nach einem der Ansprüche 8 bis 12, wobei eine Vielzahl von Kerben (108) eine generelle Sägezahn-Anordnung bildet.

- 20 5. Matériau à surface de frottement selon l'une des revendications précédentes, dans lequel ladite pluralité d'encoches (108) définit une configuration généralement en forme de dents de scie.

14. Verfahren nach einem der Ansprüche 8 bis 13, wobei die Vielzahl von Kerben (108) jeweils eine dreieckige Form aufweist.

- 25 6. Matériau à surface de frottement selon la revendication 1 ou 2, dans lequel lesdites entailles (109) sont agencées de sorte qu'elles peuvent être tirées pour former et adapter la bande (107) sur l'élément de frottement (10, 92).

15. Verfahren nach einem der Ansprüche 8 bis 14, wobei die Kerben (108) durch Biegen des Streifens (106) zusammengefügt werden.

- 30 7. Matériau à surface de frottement selon l'une des revendications précédentes, dans lequel lesdites encoches (108) ou entailles (109) sont sensiblement parallèles les unes aux autres.

16. Verfahren nach einem der Ansprüche 8 bis 12, wobei die Einschnitte (109) durch Biegen des Streifens (107) auseinander gezogen werden.

- 35 8. Procédé de fabrication d'un élément de frottement (10, 92), ledit procédé comportant les étapes consistant à :

17. Verfahren nach einem der Ansprüche 8 bis 16, wobei die Kerben (108) oder Einschnitte (109) im Wesentlichen parallel zueinander verlaufen.

- fournir un élément de frottement (10, 92),
- fabriquer un matériau à surface de frottement en tissant une pluralité de fils selon un motif prédéterminé de manière à former un matériau ayant une texture avec une pluralité de plateaux et de points bas,
- fixer lesdits fils tissés en position,
- stratifier un adhésif sur ledit matériau, ébaucher le matériau à surface de frottement sous la forme d'une bande (106, 107) comportant une pluralité d'encoches (108) ou d'entailles (109),
- cintrer la bande (106, 107) pour adapter la bande (106, 107) de matériau à surface de frottement sur ledit élément de frottement (10, 92).

18. Verfahren nach einem der Ansprüche 8 bis 17, wobei das Reibungsbauteil eine Kupplungsscheibe (92) beinhaltet.

19. Verfahren nach einem der Ansprüche 8 bis 17, wobei das Reibungsbauteil einen Sperring (10) beinhaltet.

#### Revendications

- 50 1. Matériau à surface de frottement destiné à adhérer sur un élément de frottement (10, 92) ayant la forme d'une bande (106, 107) fabriquée à partir d'une pluralité de fils tissés agencés selon un motif prédéterminé de manière à former un matériau ayant une texture avec une pluralité de plateaux et de points bas, un adhésif étant stratifié sur ledit matériau, caractérisé en ce que la bande comporte une plura-

- 55 9. Procédé selon la revendication 8, dans lequel le matériau à surface de frottement est ébauché selon ladite bande (106, 107) ayant les encoches (108) ou les entailles (109).

10. Procédé selon la revendication 8 ou 9, dans lequel la bande (106) est cintrée de sorte qu'une première extrémité de la bande (106) est amenée vers une seconde extrémité de la bande (106). 5
11. Procédé selon l'une des revendications 8 à 10, dans lequel ledit procédé comporte, de plus, les étapes consistant à : placer ledit matériau à surface de frottement (106, 107) sur une matrice ; presser ledit matériau à surface de frottement sur ledit élément de frottement à l'aide d'un poinçon. 10
12. Procédé selon la revendication 11, dans lequel ledit procédé comporte, de plus, l'étape consistant à provoquer une différence de température entre ladite matrice et ledit poinçon. 15
13. Procédé selon l'une des revendications 8 à 12, dans lequel ladite pluralité d'encoches (108) définit une configuration généralement en dents de scie. 20
14. Procédé selon l'une des revendications 8 à 13, dans lequel ladite pluralité d'encoches (108) comporte chacune une forme triangulaire. 25
15. Procédé selon l'une des revendications 8 à 14, dans lequel les encoches (108) sont rassemblées lors du cintrage de la bande (106).
16. Procédé selon l'une des revendications 8 à 12, dans lequel les entailles (109) sont tirées lors du cintrage de la bande (107). 30
17. Procédé selon l'une des revendications 8 à 16, dans lequel les encoches (108) ou entailles (109) sont sensiblement parallèles les unes aux autres. 35
18. Procédé selon l'une des revendications 8 à 17, dans lequel l'élément de frottement est constitué d'un disque d'embrayage (92). 40
19. Procédé selon l'une des revendications 8 à 17, dans lequel l'élément de frottement est constitué d'une bague de friction (10). 45
